

These exercises are designed to help you practice conditional statements. Start with the easier exercises and work your way through the challenges. Try to write the programs yourself before looking for help.

Basic Practice

Exercise 1: Age Checker

Create a variable called age. Print:

- "Child" if age is below 13.
- "Teenager" if age is 13–17.
- "Adult" if age is 18 or older.

Test your program with at least three different ages.

Exercise 2: Number Checker

Create a variable called number. Print:

- "Positive" if the number is greater than 0.
- "Negative" if the number is less than 0.
- "Zero" if the number is exactly 0.

Exercise 3: Weather Checker

Create a variable called temperature. Print:

- "Very cold" if below 10.
- "Cold" if 10–19.
- "Warm" if 20–29.
- "Hot" if 30 or above.

Exercise 4: Grade Checker

Create a variable called score. Print:

- "A" for 80 or above.
- "B" for 70–79.
- "C" for 60–69.
- "D" for 50–59.
- "Fail" for anything below 50.

Challenge: Think carefully about the order of your conditions.

Exercise 5: Traffic Light

Create a variable called light and give it one of these values: "red", "yellow", or "green".

- "Stop" for red.
- "Get ready" for yellow.
- "Go" for green.
- "Invalid light" for anything else.

Exercise 6: Password Check

Create a variable called password. If the password is exactly "python123", print "Access granted". Otherwise, print "Access denied".

Exercise 7: Simple Calculator

Create two number variables and an operator variable.

```
number1 = 10
number2 = 5
operator = "+"
```

- + → addition
- - → subtraction
- * → multiplication
- / → division
- Anything else → Invalid operator

Print the result of the operation.

Exercise 8: Movie Ticket Price

Create a variable called age. Decide the ticket price:

- Below 5 → Free
- 5-12 → 300
- 13-17 → 500
- 18 and above → 800

Print a message showing the appropriate price.

Exercise 9: What Will It Print?

Do not run the program immediately. First predict the output.

```
1 score = 85
2
3 if score >= 50:
4     print("Passed")
5 elif score >= 80:
6     print("Excellent")
7 else:
8     print("Failed")
```

FROM BASICS TO JUNIOR PYTHON DEV: Conditionals

What will it print? Why does Python not print "Excellent"? Rearrange the conditions so that 85 prints "Excellent".

Exercise 10: Follow the Conditions

Predict the output for each value of number before running the program.

```
3 number = 12
4
5 if number > 20:
6     print("A")
7 elif number > 10:
8     print("B")
9 elif number > 5:
10    print("C")
11 else:
12    print("D")
```

Then test the program with: 25, 15, 8, and 3.

Exercise 11: Find the Problem

The programmer wants a score of 90 to print "Excellent", but something is wrong with the order of the conditions.

```
3
4 score = 95
5
6 if score >= 50:
7     print("Passed")
8 elif score >= 90:
9     print("Excellent")
10 else:
11     print("Failed")
```

Fix the program so that a score of 90 or above prints "Excellent", while a score from 50–89 prints "Passed".

Exercise 12: Number Range

Create a variable called number and classify it as:

- Less than 0 → Negative
- 0–10 → Small
- 11–100 → Medium
- Above 100 → Large

Exercise 17: Mini Challenge — Student Result

Create variables for a student's name and score. The program should:

- Print the student's name.
- Give the student a grade using the grade ranges from Exercise 4.
- Print whether the student passed or failed.

Try to make the output easy for another person to read.

Exercise 18: Build Your Own

Create your own small program that uses `if`, `elif`, and `else`. Your program should have at least three possible outcomes. Choose any topic you like — games, weather, shopping, school, music, or anything else.

Write a short comment explaining what each condition is checking.
